# Introduction to the Theory of Statistics Part 2 PM522b

#### Meredith Franklin

Division of Biostatistics, University of Southern California

Slides 2, 2019

### Topics covered

Data Reduction (CB Ch. 6)

- 1. Statistics
- 2. The Sufficiency Principle
- 3. The Likelihood Principle
- 4. The Equivariance Principle

### A Statistic

- ► The random samples we generated previously are vectors of observations that can be interpreted in statistically meaningful ways
- ► We want to use the information contained in our random sample to arrive at conclusions regarding our population
- A statistic:
  - is a form of data reduction
  - can be thought of as a partition of the sample space
  - is a summary quantity of our random sample
  - is a function of the sample

### A Statistic is a Form of Data Reduction

▶ Data reduction means that we use a statistic  $T(\mathbf{x})$  instead of the entire sample  $\mathbf{x} = (x_1, ..., x_n)$  to make inferences about an unknown parameter  $\theta$ .

### Partitioning the sample space

The sample space  $\mathcal X$  can be partitioned and subsequently the observations  $\mathbf x$  can be reduced.

Let  $\mathcal{T} = \{t : t = \mathcal{T}(\mathbf{x}) \text{ for some } \mathbf{x} \in \mathcal{X}\}$  be the image of  $\mathcal{X}$  under  $\mathcal{T}(\mathbf{x})$ . Then, the statistic  $\mathcal{T}(\mathbf{x})$  partitions the sample space  $\mathcal{X}$  into sets  $A_t, t \in \mathcal{T}$  where  $A_t = \{\mathbf{x} : \mathcal{T}(\mathbf{x}) = t\}$  for  $t \in \mathcal{T}$ 

- ▶ So, rather than reporting the whole sample **x** we use  $T(\mathbf{x}) = t$
- ▶ Reporting  $T(\mathbf{x}) = t$  is equivalent to reporting  $\mathbf{x} \in A_t$

M. Franklin (USC) PM522b Slides 2, 2019 4 / 40

Statistics

# Partitioning the Sample Space

As an example of partitioning the sample space, toss a coin three times and let  $X_1, X_2, X_3$  be the outcome of each toss. So,  $X_1, X_2, X_3 \sim \text{Bernoulli}(\theta)$ . Let  $T = \sum_{i=1}^3 X_i$ . What is the partition of our sample space?

M. Franklin (USC) PM522b Slides 2, 2019 5 / 40

# A statistic is a function of the sample

- ► A statistic is formally defined as a function of the observable random variables in a sample and known constants.
- ▶ Functions of observed samples (i.e. data) are used to generate statistics.

#### Definition

For an iid sequence of random variables  $X_1, X_2, ..., X_n$  sampled from our population with distribution function  $f(\mathbf{X}|\theta)$ , the function  $T(\mathbf{X}) = T(X_1, X_2, ..., X_n)$  which does not contain the unknown parameter  $\theta$  is called a *statistic*.

M. Franklin (USC) PM522b Slides 2, 2019 6 / 40

# A statistic is a function of the sample

- ▶ The statistic T(X), a function of random variables, is itself a random variable.
- ▶ When  $T(\mathbf{X})$  is used for inference, two different random samples  $\mathbf{x}$  and  $\mathbf{y}$  that satisfy  $T(\mathbf{x}) = T(\mathbf{y})$  lead to the same inference.
- ► The most frequently used statistics are measures of central tendency and measures of concentration or variation of the random sample.

### Simple Examples

Where 
$$T(X) = T(X_1, X_2, ..., X_n)$$

$$T(X)=\bar{X}=\frac{1}{n}\sum_{i=1}^n X_i \text{ (sample mean)}$$
 
$$T(X)=S^2=\frac{1}{n-1}\sum_{i=1}^n (X_i-\bar{X})^2 \text{ (sample variance)}$$

$$T(X) = M_n$$
 (sample median)

M. Franklin (USC) PM522b Slides 2, 2019 7 / 40

### Statistic

- A statistic can be basically anything, but the choice of what we use as a statistic depends on the problem at hand.
- ► Some important things to note:
  - T need not be a continuous function, but it does need to be measurable, i.e. the mapping  $T: \mathcal{X} \to \mathcal{T}$  is measurable.
  - By saying it cannot depend on parameter  $\theta$ , that means that the parameter  $\theta$  cannot appear in the formula for T. However, it is ok if the distribution of T depends on  $\theta$ .
- ▶ Often we are interested in the distribution of T. Example from Slides 1: If  $X_1,...,X_n \sim N(\mu,\sigma^2)$  then  $\bar{X} \sim N(\mu,\sigma^2/n)$ . Another example, If  $X_1,...,X_n \sim \Gamma(\alpha,\beta)$  then  $\bar{X} \sim \Gamma(n\alpha,\beta/n)$ . We derive this result from the mgf:

$$M_{\bar{X}} = E[e^{t\bar{X}}] = E[e^{\sum X_i t/n}] = \prod_i E[e^{X_i t/n}]$$
  
=  $[M_X(t/n)]^n = [(\frac{1}{1 - \beta t/n})^{\alpha}]^n = [\frac{1}{1 - \beta/nt}]^{n\alpha}$ 

Which is the mgf of  $\Gamma(n\alpha, \beta/n)$ 

# Principles of Data Reduction

- ► We need to evaluate how good a statistic really is, and to do this we rely on the three principles of data reduction:
  - Sufficiency
  - Likelihood
  - Equivariance

We assess our statistic for certain properties:

- ▶ Does the statistic retain all of the information about the true population parameters?
- ► Has some information about our parameters been lost or obscured through the process of reducing our data?
- A sufficient statistic for  $\theta$  is one that captures all of the information about  $\theta$  contained in our sample.
- ▶ This leads to the sufficiency principle:

### Sufficiency Principle, CB 6.2

If  $T(\mathbf{X})$  is a sufficient statistic for  $\theta$ , then inference about  $\theta$  should depend on the sample  $\mathbf{X}$  only through the value of the statistic  $T(\mathbf{X})$ . If  $\mathbf{x}$  and  $\mathbf{y}$  are two sample points such that  $T(\mathbf{x}) = T(\mathbf{y})$ , the inference about  $\theta$  should be the same whether  $\mathbf{X} = \mathbf{x}$  or  $\mathbf{Y} = \mathbf{y}$  is observed.

Basically, if we know the value of the sufficient statistic T we can do just as good of a job estimating  $\theta$  as someone who knows the entire sample.

R.A. Fisher published an article in 1922 in Philosophical Transactions of the Royal Society stating that a statistic is sufficient if "no other statistic that can be calculated from the same sample provides any additional information as to the value of the parameter".

#### Definition: Sufficient statistics

For a random sample  $X_1, X_2, ..., X_n$  with pdf  $f(\mathbf{x}|\theta)$ , the statistic  $T(\mathbf{X})$  is said to be sufficient if the conditional distribution of  $X_1, X_2, ..., X_n$  given  $T(\mathbf{X})$  does not depend on  $\theta$ .

- A statistic T(X) is sufficient for  $\theta$  if inferences about  $\theta$  depend on X only through T(X). (Informal definition)
- A statistic  $T(\mathbf{X})$  is sufficient for  $\theta$  if the conditional distribution of  $\mathbf{X}$  given  $T(\mathbf{X})$  does not depend on  $\theta$ . (Formal definition)

M. Franklin (USC) PM522b Slides 2, 2019 12 / 40

### Example

To illustrate sufficiency, we devise a scenario where we have two 522b students A and B. Student A knows the entire random sample  $X_1,...,X_n=\mathbf{x}$  and can compute the statistic  $T(\mathbf{X})=t(\mathbf{x})$ . This student can make inference about the parameter  $\theta$  using this information. On the other hand, student B only knows the value of the statistic  $T(\mathbf{X})=t(\mathbf{x})$ . Since the conditional distribution of  $X_1,...,X_n$  given  $T(\mathbf{X})$  does not depend on  $\theta$ , student B knows  $P(\mathbf{X}=\mathbf{y}|T(\mathbf{X})=t(\mathbf{x}))$ , which is a probability distribution on  $A_{T(\mathbf{x})}=\{\mathbf{y}:T(\mathbf{y}=T(\mathbf{x}))\}$  that can be calculated without knowledge of the true value of  $\theta$ . So, student B can use this distribution to generate a radom sample  $\mathbf{y}$  satisfying

 $P(\mathbf{Y} = \mathbf{y} | T(\mathbf{X}) = t(\mathbf{x})) = P(\mathbf{X} = \mathbf{y} | T(\mathbf{X}) = t(\mathbf{x}))$ . This means that for each  $\theta$ ,  $\mathbf{X}$  and  $\mathbf{Y}$  have he same unconditional pdf (shown on next slide).

Student B knows just as much about  $\theta$  via  $T(\mathbf{X}) = t(\mathbf{x})$  as student A who knows the entire sample  $\mathbf{X} = \mathbf{x}$ .

M. Franklin (USC) PM522b Slides 2, 2019 13 / 40

#### Example, con't

For this example to work,  $\mathbf{X}$  and  $\mathbf{Y}$  must have he same unconditional distribution, namely  $P_{\theta}(\mathbf{X} = \mathbf{x}) = P_{\theta}(\mathbf{Y} = \mathbf{x}) \ \forall \mathbf{x}$  and  $\theta$ .

$$P_{\theta}(\mathbf{X} = \mathbf{x}) = P_{\theta}(\mathbf{X} = \mathbf{x} \text{ and } T(\mathbf{X}) = T(\mathbf{x}))$$

$$= P(\mathbf{X} = \mathbf{x} | T(\mathbf{X}) = T(\mathbf{x}))P_{\theta}(T(\mathbf{X}) = T(\mathbf{x}))$$

$$= P(\mathbf{Y} = \mathbf{x} | T(\mathbf{X}) = T(\mathbf{x}))P_{\theta}(T(\mathbf{X}) = T(\mathbf{x}))$$

$$= P_{\theta}(\mathbf{Y} = \mathbf{x} \text{ and } T(\mathbf{X}) = T(\mathbf{x}))$$

$$= P_{\theta}(\mathbf{Y} = \mathbf{x})$$

M. Franklin (USC) PM522b Slides 2, 2019 14 / 40

To verify that a statistic  $T(\mathbf{X})$  is indeed sufficient for parameter  $\theta$ , we must verify that for any fixed values of  $\mathbf{x}$  and t,  $P_{\theta}(\mathbf{X} = \mathbf{x} | T(\mathbf{X}) = T(\mathbf{x}))$ .

#### Theorem, CB 6.2.2

 $T(\mathbf{X})$  is sufficient for  $\theta$  iff the ratio  $p(\mathbf{x}|\theta)/q(T(\mathbf{x}|\theta))$  is independent of  $\theta$  where  $p(\mathbf{x}|\theta)$  and  $q(T(\mathbf{x}|\theta))$  are the joint pmfs or pdfs of  $\mathbf{X}$  and  $T(\mathbf{X})$ , respectively.

$$\begin{aligned} P_{\theta}(\mathbf{X} = \mathbf{x} | T(\mathbf{X}) &= T(\mathbf{x})) = \frac{P_{\theta}(\mathbf{X} = \mathbf{x} \text{ and } T(\mathbf{X}) = T(\mathbf{x}))}{P_{\theta}(T(\mathbf{X}) = T(\mathbf{x}))} \\ &= \frac{P_{\theta}(\mathbf{X} = \mathbf{x})}{P_{\theta}(T(\mathbf{X}) = T(\mathbf{x}))} \\ &= \frac{p(\mathbf{x} | \theta)}{q(T(\mathbf{x} | \theta))} \end{aligned}$$

M. Franklin (USC) PM522b Slides 2, 2019 15 / 40

A couple of examples:

### Sufficiency of sample mean for the normal distribution

Given  $X_1, ..., X_n$  iid  $N(\mu, \sigma^2)$  with  $\sigma^2$  known, is the sample mean,  $\bar{X} = (X_1, ..., X_n)/n$  a sufficient statistic for  $\mu$ ?

The joint pdf for the sample **X** is

$$f_X(\mathbf{x}|\mu) = \prod_{i=1}^n (2\pi\sigma^2)^{-1/2} \exp(-(x_i - \mu)^2/(2\sigma^2))$$

$$= (2\pi\sigma^2)^{-n/2} \exp(-\sum_{i=1}^n (x_i - \mu)^2/(2\sigma^2))$$

$$= (2\pi\sigma^2)^{-n/2} \exp(-\sum_{i=1}^n (x_i - \bar{x} + \bar{x} - \mu)^2/(2\sigma^2)) \text{ (add and subtract } \bar{x})$$

$$= (2\pi\sigma^2)^{-n/2} \exp(-\sum_{i=1}^n (x_i - \bar{x})^2 + n(\bar{x} - \mu)^2/(2\sigma^2))$$

M. Franklin (USC) PM522b Slides 2, 2019 16 / 40

#### Sufficiency of sample mean for the normal distribution, con't

The joint pdf for the sample mean  $\bar{X}$  which is iid  $N(\mu, \sigma^2/n)$  is:

$$f_{\bar{X}}(\bar{\mathbf{x}}|\mu) = (2\pi\sigma^2/n)^{-1/2} \exp(-n(\bar{x}-\mu)^2/(2\sigma^2))$$

So the ratio  $p(\mathbf{x}|\theta)/q(T(\mathbf{x}|\theta))$  is  $f_X(\mathbf{x}|\mu)/f_{\bar{X}}(\bar{\mathbf{x}}|\mu)$  which expands to:

$$\frac{f_X(\mathbf{x}|\mu)}{f_{\bar{X}}(\bar{\mathbf{x}}|\mu)} = \frac{(2\pi\sigma^2)^{-n/2} \exp(-\sum_{i=1}^n (x_i - \bar{x})^2 + n(\bar{x} - \mu)^2/(2\sigma^2))}{(2\pi\sigma^2/n)^{-1/2} \exp(-n(\bar{x} - \mu)^2/(2\sigma^2))}$$

$$= n^{-1/2} (2\pi\sigma^2)^{-(n-1)/2} \exp(-\sum_{i=1}^n (x_i - \bar{x})^2/(2\sigma^2))$$

and does not depend on  $\mu$ . Thus the sample mean is a sufficient statistic for the parameter  $\mu$ .

M. Franklin (USC) PM522b Slides 2, 2019 17 / 40

# Sufficiency with order statistics

Sometimes we can't reduce the sample and have to resort to other means for determining sufficiency.

#### Sufficiency when density is unknown

Let  $X_1, ..., X_n$  be iid with pdf f(x) which is unknown. The best we can do in this case is show that the order statistics  $X_{(1)}, ..., X_{(n)}$  are sufficient for f(x). (Example in class)

M. Franklin (USC) PM522b Slides 2, 2019 18 / 40

### Factorization Theorem

#### **Theorem**

A statistic  $T(\mathbf{X})$  is sufficient for  $\theta$  iff there exists functions  $g(t|\theta)$  and  $h(\mathbf{x})$  such that the joint pdf or pmf,  $f(\mathbf{x}|\theta)$  can be written as:

$$f(\mathbf{x}|\theta) = g(T(\mathbf{x})|\theta)h(\mathbf{x})$$

Proof (discrete case):

$$f(\mathbf{x}|\theta) = P_{\theta}(\mathbf{X} = \mathbf{x}) = P_{\theta}(\mathbf{X} = \mathbf{x} \text{ and } T(\mathbf{X}) = T(\mathbf{x}))$$
$$= P_{\theta}(T(\mathbf{X}) = T(\mathbf{x}))P(\mathbf{X} = \mathbf{x}|T(\mathbf{X}) = T(\mathbf{x}))$$
$$= g(T(\mathbf{x})|\theta)h(\mathbf{x})$$

M. Franklin (USC) PM522b Slides 2, 2019 19 /

# Factorization Theorem and Exponential Families

- ▶ It is easy to find sufficient statistics for exponential family distributions using the Factorization Theorem.
- ▶ Exponential families are described in CB 3.4. They include many of the most common distributions (both discrete and continuous): normal, exponential, gamma, chi-squared, beta, Dirichlet, binomial, Bernoulli, negative binomial, Poisson, Wishart, Inverse Wishart.

### **Exponential Families**

Distributions belonging to the exponential family can be expressed as:

$$f(x|\theta) = h(x)c(\theta)exp(\sum_{i=1}^{k} w_i(\theta)t_i(x))$$

Where  $h(x) \ge 0$  and  $t_1(x), ..., t_k(x)$  are real valued funtions of the observations x (they cannot depend on  $\theta$ ),  $c(\theta) \ge 0$ , and  $w_1(\theta), ..., w_k(\theta)$  are real valued functions of the paramter(s)  $\theta$  (they cannot depend on x).

M. Franklin (USC) PM522b Slides 2, 2019 20 / 40

# Factorization Theorem and Exponential Families

- ▶ The important thing to notice is what characterizes the exponential family distributions—the parameter(s) and observation variable(s) must factorize.
- ► This means the distribution can be separated into products that each involve either the parameters or the observations.
- ▶ To verify that a pdf or pmf belongs to the exponential family, the functions h(x),  $c(\theta)$ ,  $w_i(\theta)$  and  $t_i(\theta)$  must be identified and shown to have the form shown above.
- ▶ Example in class of exponential family  $N(\mu, \sigma^2)$

M. Franklin (USC) PM522b Slides 2, 2019 21 / 40

# Factorization Theorem and Exponential Families

### Sufficiency, Factorization Theorem and Exponential Families

Let  $X_1,...,X_n$  be iid observations from a pdf or pmf  $f(x|\theta)$  that belongs to an exponential family:

$$f(x|\theta) = h(x)c(\theta)exp(\sum_{i=1}^{k} w_i(\theta)t_i(x))$$

where  $\theta = (\theta_1, ..., \theta_d)$ ,  $d \leq k$ .

Then

$$T(\mathbf{X}) = (\sum_{j=1}^{n} t_1(X_j), ..., \sum_{j=1}^{n} t_k(X_j))$$

is sufficient for  $\theta$ .

Examples in class of Poisson and normal exponential family factorization for finding sufficient statistics.

M. Franklin (USC) PM522b Slides 2, 2019 22 / 40

- As we shave seen, there are cases where there are many sufficient statistics for a particular model.
- Sufficient statistics are not unique. If T(X) is sufficient and  $T^*(X)$  is another statistic such that  $T(X) = g_1(T^*(X))$  for some function  $g_1$  then  $T^*(X)$  is also sufficient.

$$f(x|\theta) = g(T(x)|\theta)h(x)$$
  
=  $g(g_1(T^*(x))|\theta)h(x)$   
=  $g^*(T^*(x)|\theta)h(x)$ 

- ▶ So if T(X) is sufficient, so is  $T^*(X) = (T(X), T_1(X))$  where  $T_1(X)$  is any other statistic.
- ▶ If  $T(X) = g_1(T^*(X))$  then the partition of  $\mathcal{X}$  defined by T(x) is coarser than that defined by  $T^*(x)$ .

M. Franklin (USC) PM522b Slides 2, 2019 23 / 40

- ▶ Given many possible sufficient statistics, are some better than others?
- ▶ Recall we want a statistic that provides data reduction without loss of information about the parameter  $\theta$ . Thus, a statistic that achieves the most data reduction while retaining all the information about  $\theta$  is preferable. Such a statistic is called a minimal sufficient statistic.

#### Minimal Sufficient Statistic

T(X) is a minimal sufficient statistic if it is sufficient and for any other sufficient statistic  $T^*(X)$ , T(X) is a function of  $T^*(X)$ .

▶ However, this definition of minimal sufficient statistics does not often help identify which of a group of sufficient statistics is actually minimal (normal model example).

M. Franklin (USC) PM522b Slides 2, 2019 24 / 40

#### Theorem for Minimal Sufficient Statistics

If T(X) has the property that the ratio  $f(x|\theta)/f(y|\theta)$  does not depend on  $\theta$  iff T(x) = T(y) then T(X) is a minimal sufficient statistic for  $\theta$ .

Proof:

Let T(X) satisfy the condition of the theorem. We show that T(X) is sufficient and that it is minimally sufficient.

Let  $x_t$  denote an element of  $A_t$ . Recall  $A_t = \{x : T(x) = t\}$ . So,  $T(x_t) = t$  and  $T(x_{T(x)}) = T(x)$ 

from the theorem, we have:

$$\frac{f(x|\theta)}{f(x_{T(x)}|\theta)} = h(x)$$

where h(x) is some function that does not depend on  $\theta$ .

$$f(x|\theta) = f(x_{T(x)}|\theta)h(x)$$

So by the factorization theorem, T(X) is sufficient.

M. Franklin (USC) PM522b Slides 2, 2019 25 / 40

#### Theorem for Minimal Sufficient Statistics, con't

Let  $T^*(X)$  be another sufficient statistic. By the factorization theorem we have

$$\frac{f(x|\theta)}{f(y|\theta)} = \frac{h^*(x)g^*(T^*(x)|\theta)}{h^*(y)g^*(T^*(y)|\theta)} = \frac{h^*(x)}{h^*(y)}$$

Thus  $T^*(x) = T^*(y)$  implies that  $f(x|\theta)/f(y|\theta)$  does not depend on  $\theta$ . From the assumption that T(x) = T(y) it follows that the partition of  $\mathcal X$  induced by  $T^*(x)$  is finer than that induced by T(X). This implies that T(X) is a minimal sufficient statistic.

M. Franklin (USC) PM522b Slides 2, 2019 26 / 40

Some general notes about sufficiency and minimal sufficiency:

- In terms of partitioning the sample space, any sufficient statistic introduces a partition of the sample space.
- ▶ The partition of the minimal sufficient statistic is the **coarsest** so that it achieves the greatest possible data reduction for a sufficient statistic.
- A minimal sufficient statistic eliminates all of the extra information in the sample and leaves only that which contains information about  $\theta$ .

PM522h Slides 2, 2019 27 / 40

#### An ancillary statistic:

- $\triangleright$  contains no information about parameter  $\theta$ ; however, it provides a complimentary purpose to a sufficient statistic.
- ▶ An ancillary statistic by itstelf does not provide any information about a parameter, but in conjunction with another statistic it can (R.A. Fisher).
- ightharpoonup is an observation on a random variable whose distribution is fixed and known, but unrelated to  $\theta$ .
- ightharpoonup is denoted as S(X)

The range statistic  $R = X_{(n)} - X_{(1)}$  is a common example of an ancillary statistic because it does not depend on the distribution of the sample  $\mathbf{x}$  but rather on the parameter of the distribution that relates to *location*.

Other examples include ancillary statistics belonging to the scale family, or a mixture of scale and location.

M. Franklin (USC) PM522b Slides 2, 2019 28 / 40

Location family  $\theta$  is the location parameter:

$$\{F(x-\theta): -\infty < \theta < \infty\}$$

Scale family  $\theta$  is the scale parameter:

$$\{(1/\theta)F(x/\theta):\theta>0\}$$

Scale-Location family  $\theta_1$  is the scale parameter and  $\theta_2$  is the location parameter:

$$\{(1/\theta_1)F((x-\theta_2)/\theta_1): \theta_1 > 0, -\infty < \theta_2 < \infty\}$$

M. Franklin (USC) PM522b Slides 2, 2019 29 / 40

### Location Ancillary Statistics

We use the CDF to show how location ancillary statistics do not depend on the parameter  $\theta$ . Let  $X_1,...,X_n$  be iid observation from a location parameter family with cdf  $F(x-\theta)$ . Let  $Z_1,...,Z_n$  be iid observations with cdf F(x) (i.e.  $\theta$ =0) with  $X_1 = Z_1 + \theta,...,X_n = Z_n + \theta$ . Show the range  $R = X_{(n)} - X_{(1)}$  is an ancillary statistic.

The cdf of R is

$$F(r|\theta) = P(R \le r)$$

$$= P(\max X_i - \min X_i \le r)$$

$$= P(\max(Z_i + \theta) - \min(Z_i + \theta) \le r)$$

$$= P(\max Z_i - \min Z_i + \theta - \theta \le r)$$

$$= P(\max Z_i - \min Z_i < r)$$

Which does not depend on  $\theta$  because the distribution of  $Z_1,...,Z_n$  does not depend on  $\theta$ .

In class example showing the range for  $\mathsf{Uniform}(\theta, \theta+1)$  is an ancillary statistic.

30 / 40

### Scale Ancillary Statistics

Again we use the CDF to show how scale ancillary statistics do not depend on the parameter  $\theta$ . Let  $X_1,...,X_n$  be iid observation from a scale parameter family with cdf  $F(x/\theta)$ . Any statistic that depends on the sample through its n-1 values  $X_1/X_n,...X_{n-1}/X_n$  is an ancillary statistic.

Let  $Z_1,...,Z_n$  be iid observations with cdf F(x) (i.e.  $\theta=1$ ) with  $X_i=\theta Z_i$ . The joint CDF of  $X_1/X_n,...X_{n-1}/X_n$  is:

$$F(y_1, ..., y_{n-1}|\theta) = P(X_1/X_n \le y_1, ..., X_{n-1}/X_n \le y_{n-1})$$

$$= P(\theta Z_1/(\theta Z_n) \le y_1, ..., \theta Z_{n-1}/(\theta Z_n) \le y_{n-1})$$

$$= P(Z_1/Z_n \le y_1, ..., Z_{n-1}/Z_n \le y_{n-1})$$

Which does not depend on  $\theta$  because the distribution of  $Z_1,...,Z_n$  does not depend on  $\theta$ .

M. Franklin (USC) PM522b Slides 2, 2019 31 / 40

### Location and Scale Families

#### Examples of Location families:

- ▶ Uniform  $(\theta, \theta + 1)$  with pdf  $f(x|\theta) = I(\theta \le x \le \theta + 1)$
- ► Cauchy location family with pdf  $f(x|\theta) = \frac{1}{\pi(1+(x-\theta)^2)}$
- ▶  $N(\mu, \sigma^2)$  with  $\mu$  unknown and  $\sigma^2 > 0$  known

### Examples of Scale families

- ▶ Uniform  $(0,\theta)$  with pdf  $f(x|\theta) = \theta^{-1}I(0 \le x \le \theta)$
- ► Cauchy location family with pdf  $f(x|\theta) = \frac{1}{\theta \pi (1 + (x/\theta)^2)}$
- ▶  $N(0, \sigma^2)$  with  $\sigma^2 > 0$  unknown
- ▶ Exp( $\beta$ ) with pdf  $f(x|\beta) = \beta^{-1}e^{-x/\beta}I(x \ge 0)$

### Examples of Location-Scale families:

- ▶ Uniform  $(\alpha,\beta)$
- ▶ Normal  $N(\mu, \sigma^2)$  both parameters unknown

M. Franklin (USC) PM522b Slides 2, 2019 32 / 40

# Complete Statistics

Ancillary statistics in conjunction with sufficient statistics provides us with a definition for complete statistics.

Basically, if we have a sufficient statistic that optimally summarizes the observations, then there should not be an ancillary statistic that is a function of that statistic.

#### Basu's Theorem

If T(X) is complete and a minimal sufficient statistic then T(X) is independent of every ancillary statistic.

(i.e. A complete sufficient statistic is independent of every ancillary statistic.)

(Proof in class)

# Complete Statistics

Complete statistics apply to families of distributions, most importantly the exponential family.

### Complete Statistics in the Exponential Family

Let  $X_1, ..., X_n$  be observations from an exponential family with pdf (or pmf) that has the form

$$f(x|\theta) = h(x)c(\theta) \exp(\sum_{j=1}^{k} w(\theta_j)t_j(x))$$

where  $\theta = (\theta_1, \theta_2, ..., \theta_k)$ . Then the statistic

$$T(X) = (\sum_{i=1}^{n} t_1(X_i), \sum_{i=1}^{n} t_2(X_i), \dots, \sum_{i=1}^{n} t_k(X_i))$$

is complete as long as the parameter space  $\Theta$  contains an open set in  $\Re^k$ 

M. Franklin (USC) PM522b Slides 2, 2019 34 / 40

# Sufficient, Minimal, and Complete Statistics

Sufficiency and completeness is used in constructing estimators of parameters  $\theta$  such as the maximum likelihood estimator and Bayes estimators.

- Suppose that T is sufficient for  $\theta$  and there exists a maximum likelihood estimator of  $\theta$ . Then, there exists a maximum likelihood estimator U that is a function of T.
- ▶ Rao-Blackwell Theorem: Suppose that T is sufficient for  $\theta$  and that W is an unbiased estimator of  $\tau(\theta)$ . Then  $E_{\theta}(W|T)$  is a statistic and is uniformly better than W as an estimator of  $\tau(\theta)$ .
- Lehmann-Scheffe Theorem: Suppose that T is sufficient and complete for  $\theta$  and that  $W = \phi(T)$  is an unbiased estimator of  $\tau(\theta)$ . Then W is a uniformly minimum variance unbiased estimator (UMVUE) of  $\tau(\theta)$ .

### Likelihood

First we need to go over the likelihood principle:

- Likelihoods relate data to a population.
- ► They arise from a probability distribution function  $f(x|\theta)$  connecting data x to a population.
- ▶ Used as a data reduction technique.
- We assume data come from a family of distributions with unknown parameters.
- ▶ We use the data to estimate these unknown parameters.

### Likelihood

### Definition: The Likelihood Principle

The likelihood principle states that given a pdf  $f(\mathbf{x}|\theta)$  and observed data  $\mathbf{x}$ , all of the relevant information regarding the unknown parameter(s)  $\theta$  is contained in the likelihood function for the observed  $\mathbf{x}$ 

Two likelihood functions contain the same information about  $\theta$  if they are proportional to each other.

M. Franklin (USC) PM522b Slides 2, 2019 37 / 40

### Likelihood

population with pdf  $f(x|\theta_1,\theta_2,...,\theta_k)$  where  $\theta_i,i=1,...,k$  are unknown parameters.

▶ In the context of random variables,  $X_1, X_2, ..., X_n$  are an iid sample from a

- ▶ The likelihood is f viewed as a function of of  $\theta_i$  for fixed observed values of x.
- ► The joint density of the data evaluated as a function of the parameters with the data fixed

### Likelihood Function

#### Definition

Let  $f(\mathbf{x}|\theta)$  be the joint pmf or pdf of  $\mathbf{X} = X_1, X_2, ..., X_n$  (iid). Given  $\mathbf{X} = \mathbf{x}$  is observed, then the likelihood function of  $\theta$  defined is by:

$$L(\theta|\mathbf{x}) = f(\mathbf{x}|\theta)$$

for continuous X, or for discrete X:

$$L(\theta|\mathbf{x}) = P_{\theta}(\mathbf{X} = \mathbf{x})$$

# Equivariance

- ► Given some data, statistical decisions should not be affected by simple transformations or reordering of the data.
- ► For example, the value of a point estimate will be affected by a transformation, but it should be *equivariant* in the sense that it reflects the transformation in a meaningful way.
- ► This is formalized by the equivariance principle through which appropriate classes of transformations are defined and rules that statistical decisions must satisfy are specified.
